1 **ABSTRACT**

2 **Aims and objectives.** To explore hospice, acute care and nursing home nurses' experiences
3 of pain management for people with advanced dementia in the final month of life. To identify
4 the challenges, facilitators and practice areas requiring further support.

5 **Background.** Pain management in end-stage dementia is a fundamental aspect of end of life
6 care; however, it is unclear what challenges and facilitators nurses experience in practice,
7 whether these differ across care settings, and whether training needs to be tailored to the
8 context of care.

9 **Design.** A qualitative study using semi-structured interviews and thematic analysis to
10 examine data.

11 **Methods.** 24 registered nurses caring for people dying with advanced dementia were
12 recruited from ten nursing homes, three hospices, and two acute hospitals across a region of
13 the United Kingdom. Interviews were conducted between June 2014 and September 2015.

14 **Results.** Three core themes were identified: challenges administering analgesia, the nurse-
15 physician relationship, and interactive learning and practice development. Patient-related
16 challenges to pain management were universal across care settings; nurse- and organisation-
17 related barriers differed between settings. A need for interactive learning and practice
18 development, particularly in pharmacology, was identified.

19 **Conclusions.** Achieving pain management in practice was highly challenging. A number of
20 barriers were identified; however, the manner and extent to which these impacted on nurses
21 differed across hospice, nursing home and acute care settings. Needs-based training to
22 support and promote practice development in pain management in end-stage dementia is
23 required.

Relevance to clinical practice. Nurses considered pain management fundamental to end of life care provision; however, nurses working in acute care and nursing home settings may be under-supported and under-resourced to adequately manage pain in people dying with advanced dementia. Nurse-to-nurse mentoring and ongoing needs-assessed interactive case-based learning could help promote practice development in this area. Nurses require continuing professional development in pharmacology.

WHAT DOES THIS PAPER CONTRIBUTE TO THE WIDER GLOBAL COMMUNITY?

- Globally, pain management in palliative care is a health policy priority; however, it is unclear what barriers and facilitators are experienced by nurses caring for people with advanced dementia in the final month of life and whether these differ across care settings.
- Patient-related barriers to pain management were universal across nurse participants and care settings. However, the barriers arising from nurse-related and organisational factors, and extent to which they impacted on nurses' experiences of pain management, varied across acute care, hospice and nursing home care settings.
- This study identified a gap between health policy recommendations for pain management in palliative care and availability of resources to support nurses working in different healthcare settings in implementing these recommendations in clinical practice.

47 Dementia has become a leading cause of disability and a significant contributor to mortality
48 in developed countries propelling it to priority status in healthcare policy, research and
49 education globally (World Health Organisation 2012, van der Steen *et al.* 2014). A recent
50 study estimated that the prevalence of dementia worldwide has reached 46.8 million; a figure
51 expected to reach 74.7 million by 2030 (Prince *et al.* 2015). The potential impact of the
52 increasing global and local prevalence of dementia on healthcare services and staff, who will
53 be managing this population to the end of life, requires consideration. The complex pattern of
54 behavioural and cognitive deficits displayed in dementia results in a patient population whose
55 care requirements differ from those in whom these abilities remain functional. Whilst models
56 of palliative care may be extrapolated from one health context to another (e.g. the application
57 of the palliative care model for cancer to other terminal conditions), they are often not
58 appropriate for use in patients who are unable to participate in, comprehend or consent to,
59 decisions regarding their own care (Rabins and Black 2007). Institutional settings, such as
60 nursing and residential homes, hospitals and hospices, are commonly the last place of care for
61 many older adults with dementia (Ahmad & Mahoney 2005, Houttekier *et al.* 2010).
62 Understanding the barriers to and facilitators of care experienced by healthcare professionals
63 in these settings therefore becomes critical to identify areas where patient needs are not met
64 and in the development of efficient and feasible strategies which adequately support staff in
65 their practice.

66 Optimal palliative care for people with dementia, including the management of pain, has been
67 highlighted as a priority in health policy globally (Department of Health 2009, van der Steen
68 *et al.* 2014). However, evidence suggests suboptimal pain management in people with
69 dementia compared to cognitively intact older people, including under-prescribing of
70 analgesia for people with dementia in long-term care, in cancer, after hip fracture and in
71 postoperative care (Bell 1997, Horgas & Tsai 1998, Kaasalainen *et al.* 1998, Morrison & Siu

2000, Nygaard & Jarland 2005, Cornali *et al.* 2006, Reynolds *et al.* 2008, Monroe *et al.* 2013).

BACKGROUND

The prevalence of comorbidities in people with dementia often necessitates pain management throughout disease progression and into the final months of life (Mitchell *et al.* 2009, Klapwijk *et al.* 2014, Hendriks *et al.* 2015). The challenges of assessing and managing pain in this complex population have attracted sustained research attention, particularly with regards to the attitudes, knowledge and practices of nursing staff who play a significant role in pain assessment and management (Kovach *et al.* 2000, Nygaard & Jarland 2005, Kaasalainen *et al.* 2007, Zwakhalen *et al.* 2007, Barry *et al.* 2012). Nurses' attitudinal beliefs towards, and knowledge of, the presence, experience and impact of pain on older adults with and without dementia, have critical implications for assessment and treatment, and have been linked to delayed assessment of pain, suboptimal treatment and underuse of *pro re nata* (PRN) analgesia (Kovach *et al.* 2000, Nygaard & Jarland 2005, Kaasalainen *et al.* 2007, Zwakhalen *et al.* 2007, Barry *et al.* 2012).

A substantial body of compelling evidence has identified deficits in nurses' knowledge of pain assessment, pharmacology, side-effects and dosing schedules and the presence of misguided perceptions regarding the use of opioids and regularly prescribed analgesics, suggesting that nursing staff are inadequately educated on the use of analgesics in palliative care for people with dementia (Kovach *et al.* 2000, Auret & Schug 2005, Barry *et al.* 2012, Ghandehari *et al.* 2013). Poor pain management has a number of adverse outcomes for patients including the manifestation or exacerbation of neuropsychiatric symptoms, agitation, depression, challenging and resistive behaviour and sleep disturbance (Cipher & Clifford 2004, Hadjistavropoulos *et al.* 2007). Previous studies have focused on nurses' experience of

96 pain management prior to the end of life but little is known about attitudes of and competence
97 in pain management in the final weeks. A small qualitative study by Brörson and colleagues
98 (2014) explored the experiences of nurses working in a Swedish hospital dedicated to the care
99 of patients with neuropsychiatric disorders including dementia. Barriers to pain management
100 identified included difficulties obtaining analgesic prescriptions, anxiety regarding use of
101 morphine, and problems with nurse-physician communication (Brörson *et al.* 2014). To the
102 knowledge of the authors, no studies have been conducted to date which explore nurses’
103 experiences and perspectives of pain management for people with advanced dementia nearing
104 the end of life across multiple care settings including hospice, acute care and nursing home
105 contexts. This study aims to address this gap in the literature.

106

107 **AIM**

108 The aim of this research was to explore hospice, nursing home and acute care nurses’
109 experiences of pain management, the perceived barriers to and facilitators of pain
110 management, and perspectives on training needs in managing pain in people with advanced
111 dementia in the final month of life.

112

113 **METHOD**

114 **Design**

115 This qualitative study forms part of a larger programme of research aimed at exploring
116 nurses’, physicians’ and healthcare assistants’ experiences of pain assessment and
117 management for people with advanced dementia in the final month of life with a view to
118 developing a complex intervention to address clinical and professional issues identified, to

1
2
3 119 improve pain assessment and management for this vulnerable patient group. This qualitative
4
5 120 study used face-to-face, semi-structured interviews to explore nurses' experiences.

12
13
14 123 *Ethics*

15
16
17 124 Ethical approval was granted by the Office for Research Ethics Committees Northern Ireland
18
19 125 (ORECNI) (14/NI/0013). The study protocol and supporting materials were reviewed and
20
21 126 approved by independent ethics committees in the participating hospices, in one large chain-
22
23 127 owned nursing home and by the participating HSC Trusts.
24
25

26 128
27
28
29 129 *Sample and recruitment*

30
31
32 130 Registered nurses (RNs) with responsibility for caring for people with advanced dementia
33
34 131 who were nearing the end of life and/or who had died were eligible for participation. We
35
36 132 aimed to recruit a maximum variation sample (regarding age, job role, educational attainment
37
38 133 and length of clinical experience) of nurses within hospice, acute care hospital and nursing
39
40 134 home care settings. Index contacts in each of these settings were approached for participation
41
42 135 in the first instance and subsequent participants were contacted through an onward process of
43
44 136 nominative sampling. Nursing home managers and hospice medical directors distributed
45
46 137 study materials to eligible participants within their respective care settings. In acute care,
47
48 138 consultant physicians (in geriatric medicine, care of the elderly and palliative medicine)
49
50 139 distributed study information, comprising an invitation cover letter and participant
51
52 140 information sheet, to eligible nursing teams within their hospitals. All nurses who responded
53
54 141 to the participation call were recruited into the study. Twenty-four nurses were recruited from

three hospices, two acute care hospitals and ten nursing homes. These settings cover four out of the five regional Health and Social Care (HSC) Trust areas in Northern Ireland (NI), United Kingdom (UK). Recruitment ceased when no further novel data were identified in transcripts at the within-group and across-group levels and data saturation was achieved.

Data collection tools

Semi-structured, in-person interviews were conducted with nurses at their place of work. All participants provided written informed consent. An interview topic guide of open-ended questions was used; this was developed from a review of the literature and refined to suit the focus of the study. Interview topics covered: experiences of managing pain in people dying with advanced dementia, barriers to and facilitators of, pain management, and training needs. All interviews were digitally audio-recorded and transcribed verbatim. Interview duration ranged from 31 minutes to 45 minutes (average 37.9 minutes). Shorter duration interviews reflect the challenges of interviewing hospital nurses. Data were collected between June 2014 and September 2015.

Data analysis

Data management and analysis were facilitated using NVivo10 software (QSR International (UK) Ltd, Cheshire, UK). Thematic analysis using Braun and Clarke’s (2006) paradigm was the analytical approach taken to data analysis. Following several re-readings of each transcript, passages of text comprising feelings, thoughts, short narratives, perspectives and experiences were assigned descriptive codes reflecting the concepts expressed by those data. To ensure consistency, coding was performed in constant comparison to coding completed in prior transcripts and a coding frame was developed. Codes were reviewed and grouped by concept (e.g. ‘route of administration’) and then arranged by theme (e.g. ‘challenges

administering analgesia'). To identify whether differences in nurses' experiences of pain management were differentially impacted by the care setting in which they practised, analysis was performed at two levels. In the first instance, data were analysed at the level of the care-setting for each group (hospice nurses, acute care nurses and nursing home nurses) and subsequently expanded to cross-group comparison (hospice versus acute care versus nursing home).

Validity and reliability/Rigour

Recommendations from established and recent literature on demonstrating validity, reliability and rigour in qualitative research were adopted and employed throughout this study (Rolfe 2006). All interviews were transcribed verbatim by the research fellow (Initials); these were checked for accuracy against the original digital recordings by two members [Initials of academic professor 1] and [initials of Patient and Participant Involvement Representative] of the Project Management Group (PMG). Primary data analysis was performed by the research fellow, after which a selection of transcripts were independently analysed by [initials of Principal Investigator] and [initials of academic professor 1]. The process of data analysis and identification of the core themes were discussed and agreed between the three authors and presented to and discussed in bi-monthly meetings of the PMG; a group comprising two practising academic-physicians in geriatric/dementia and palliative care, four academics specialising in palliative care, nursing and palliative care and pharmacy, three General Practitioners (GPs) with a special interest in older adults, dementia and palliative care, and one Patient and Public Involvement representative (also a retired GP). An audit trail of the analysis was kept, detailing steps in the development of the coding frame and each level of analysis.

RESULTS

A total of 24 participants comprising hospice nurses (n=6), acute care nurses (n=6) and nursing home nurses (n=12) were recruited. The majority were female (n=23). Participants had an average age of 36.8 years (range: 25 to 59 years) and an average of 13.8 years' nursing experience (range: 3 months to 34 years). Seven participants had postgraduate qualifications including a diploma or master's degree in palliative care, and one participant was undertaking the first year of doctoral study in palliative nursing at the time of the study. Nurse grades ranged from staff nurse to nurse manager. Participant characteristics are presented in full in Table 1.

Table 1. Participant characteristics

Participants' experiences were characterised into three core themes: (1) challenges administering analgesia, (2) the nurse-physician relationship and (3) interactive learning and practice development. The theme "challenges administering analgesia" reflects challenges arising from the inherent complexity of the patient population (people dying with advanced dementia) and as such, nurses' experiences were universal and not differentially impacted by setting. The second and third core themes comprised both commonalities of experience across settings, with sub-themes reflecting setting-specific challenges. In these cases, experiences were common to nurses within a specific care setting (e.g. acute care) but differed from experiences of nurses in other settings (e.g. hospice). Core themes and sub-themes are presented in Table 2.

Table 2. Core themes and sub-themes identified in within-group and cross-group analysis

Challenges administering analgesia

Commonly experienced challenges with the administration of analgesia comprised patient refusal of pain relief and difficulties with routes through which analgesics could be administered.

Medication refusal

Patient refusal of analgesia (and other medications) was commonly experienced by participants with most perceiving refusal as the result of patient anxiety and/or fear regarding medication use. It was believed that profound deficits in cognition prevented patients from recognising medications as such, and impairments in communication removed the possibility of engaging in nurse-patient dialogue to explain the need for, and benefits of, analgesia, through which patients' fears and anxieties might be allayed.

It can be difficult then to explain that this is what is working for you and we think that this will help you". (NURS022 - Hospice nurse)

In some cases, patients' inability to understand the purpose of pain relief provided, combined with the pain they were experiencing, culminated in aggressive resistance to treatment.

Some of them would be aggressive, they will just full stop not take any pain relief from you and yet you know they need the pain relief. (NURS02 – Nursing home nurse)

235 Many nurses expressed deep empathy for patients, reflecting that fear and/or anxiety were
236 natural responses in dying patients who are entirely dependent on others for care and who
237 cannot understand or adequately express their needs.

238 Put yourself in the shoes of the resident, you're lying there, you can't talk, you can't
239 understand. You're really at the mercy of the people looking after you. (NURS016 -
240 Nursing home nurse)

241
242 *Route of administration*

243 Participants reported barriers to pain management in patients dying with advanced dementia
244 resulting from constraints on available and appropriate routes of administration. Oral
245 administration of analgesia was challenging in dying patients with frequent and/or excessive
246 drowsiness or who were asleep for extended periods of time. Analgesic use in tablet and
247 liquid formulations carried a high risk of aspiration pneumonia for patients with dysphagia, a
248 common feature in end-stage dementia, often necessitating a review of patients' analgesic
249 regimens.

250 The challenge is they can't take it orally a lot of the time because their swallow
251 deteriorates and they frequently get aspiration pneumonia so whatever oral pain relief
252 they would have been on previously, they can't take anymore. (NURS09 – Acute care
253 nurse)

254 Participants reported that syringe drivers, injections and intravenous administration could be
255 challenging when used for end-stage patients with dementia with low body fat, little
256 musculature and cachexia.

257 People with advanced dementia tend to have skin and bones as they haven't been

258 eating great so even like giving subcut [subcutaneous] injections or intramuscular
259 sometimes there's nowhere to put it that's not going to cause more pain whenever
260 you're administering it. (NURS020 – Acute care nurse)

261 Many expressed concern regarding the use of needles in dying patients due to beliefs that
262 these routes were painful and distressing for patients, especially for those who were already
263 anxious and/or agitated.

264 ...they can become more anxious coming near the end...if they see a needle they're
265 freaked out so you have to assess the situation, is it really worthwhile me putting such
266 and such through this here? (NURS06 – Hospice nurse)

267 Respondents preferred less invasive methods such as suppositories and transdermal patches
268 over subcutaneous and intravenous delivery in the final weeks of life and for the imminently
269 dying; these were considered to be minimally invasive with low risk of injury to patients
270 during administration.

271 We start with a patch of some description for pain relief, so that keeps them pain free.
272 I find that for people who have dementia, you don't tend to need syringe pumps,
273 you'd use paracetamol suppositories, maybe diazepam suppositories. (NURS09 –
274 Acute care nurse)

275

276 **The nurse-physician relationship**

277 *Positive relationships*

278 All hospice nurses reported positive nurse-physician relationships which were characterised
279 by mutual professional respect, trust and collaboration. They perceived themselves to be

280 working in successful partnership with medical staff towards a common goal of pain
281 management.

282 I think we're doing quite well [in managing pain], but I think it is because we have
283 such a good, you know, we have a good team and we have specialists, you know, as
284 well, I think that all ties in together. (NURS017 – Hospice nurse)

285 Just over half of nursing home nurses and acute care nurses also reported positive nurse-
286 physician relationships. These nurses perceived that physicians responded promptly to reports
287 of pain and to prescription requests, demonstrated shared goals of care, and valued nurses'
288 contribution to patient care. Open and articulate communication facilitated a collaborative
289 relationship between nurses and physicians in which disciplinary knowledge was shared to
290 meet the challenges of managing pain as well as other aspects of patient care.

291 The GPs are there all the time to help, they always go with us because they know that
292 we are the ones seeing [the patients] everyday, we know each and every difference in
293 them from yesterday, today, tomorrow. So when we explain, they have trust in us.
294 (NURS013 – Nursing home nurse)

295
296 *Difficult relationships*

297 Difficult nurse-physician relationships were reported by both nursing home and acute care
298 nurses. Some nurses felt that physicians were reluctant to conduct patient assessments and
299 ignored requests for help with complex cases.

300 Some will say: well, what's wrong with them? And try and diagnose over the phone,
301 rather than actually coming out and doing a home visit. Probably one of the biggest

issues that we have, is that the GPs wouldn't always come out and help us assess.

(NURS015 – Nursing home nurse)

Negative relationships were also reported where participants experienced difficulties or delays in obtaining scripts, where prescribing decisions were perceived (and/or transpired) to be sub-therapeutic, and where treatment appeared to be unreflective of patient needs.

Sometimes I think there's reluctance on the part of the medical [staff], especially if it's a junior medic, you know, to even prescribe something. (NURS021 – Acute care nurse)

Senior acute care and nursing home nurses felt confident in advocating for patients in cases where nurses' and physicians' goals of care were perceived to be discordant but acknowledged that confidence to query prescribing decisions varied among nurses.

Some [GPs] have their own thoughts and trends in their head and what they believe is right. I think they open a book and it says A, B, C and D to them and therefore they want to follow A, B, C and D to do their best, but sometimes they forget to listen to the nurses who do know. I think it depends on how empowered a nurse is to actually say to a GP: hold on a minute, and to be an advocate for our residents. (NURS03 – Nursing home nurse manager)

Nurses with 20 or more years' nursing experience believed that poor communication skills and inadequate reporting among nursing staff contributed to the difficulties experienced in nurse-physician relationships. Failure to provide salient, contextual information about patients (such as changes in swallow) clouded the clinical picture for physicians, especially for those not present in the care setting daily, in some cases resulting in clinical errors and/or inappropriate treatment.

325 If it's a GP writing up, their initial thing would be to write up the ordinary capsules
326 but it's the nurses being proactive to say, whenever they're getting it prescribed: "Oh
327 this patient's swallow is quite impaired, is there any other form that can be given in?"
328 So it's not the GP's fault, it's the nurses not informing them of the actual situation.
329 (NURS010 – Nursing home nurse)

330

331 **Interactive learning and practice development**

332 *Hospice nurses*

333 Hospice nurses perceived themselves to be fortunate in being able to readily access ongoing
334 professional development across many aspects of dementia care including pain management.

335 I think we are quite lucky here because we get quite a lot of training [...]. You're
336 getting your practical training, you have your mentor, and you learn so much from
337 your mentor. And then we have online training and we have certain study days
338 dedicated to it [dementia] and if we want we can get external training as well.
339 (NURS05 Hospice nurse).

340 Hospice nurses expressed preference for interactive, group discussion of patient cases
341 alongside structured didactic teaching, reporting that these approaches facilitated and
342 encouraged knowledge exchange between nursing staff.

343 Usually here we would have small groups [...] and it's very interactive and it's not
344 very formal but it's very, very, informative, very good. And then you can bounce
345 ideas off each other, it's very good I think. (NURS011 – Hospice nurse)

346

347 *Acute care and nursing home nurses*

These nurses' experiences of training and development differed substantially to those of hospice nurses. Opportunities for professional and practice development were often limited for acute care and nursing home nurses due to constraints on staff time, heavy workload and the need to travel to training events.

I think the problem with the training is the training days aren't local for the staff and there might only be one training day and not all the nurses can go on that one day. (NURS08 – Acute care nurse).

Opportunities for learning and development were also often negatively impacted by the financial resources available in their respective organisations.

...the problem is that a lot of the training is quite expensive so the nursing homes are not subscribing to it. I mean some of these training days can cost £1200 for the day. (NURS10 – Nursing home nurse)

Barriers to training and practice development resulted in some staff having received no training in dementia care including in pain management.

I haven't had any training with regards to dementia so it's just something that I'm maybe learning from colleagues. (NURS20 – Acute care nurse).

Whole-group perspectives on interactive learning and practice development

All respondents believed that access to ongoing professional development was critical in empowering staff to effectively and safely manage pain and provide a good standard of holistic care to people dying with advanced dementia. When asked to describe their preferences for training approach, the large majority believed that mentoring and/or shadowing experienced nurses constituted an ideal approach to training. Senior and less

371 experienced nurses believed that ‘leading by example’ and ‘learning by example’ were
372 methods most likely to encourage and promote professional and practice development for
373 nurses.

374 I’m saying to them think about it yourself: if co-codamol isn’t strong enough, what
375 would be your next pain relief that you would use? If someone’s on this [analgesic]
376 now, how much morphine is this? And if I had to change it, what would I do next?
377 And the staff find that approach is very helpful. (NURS05 - Hospice nurse)

378 Participants emphasised that training and practice development should be an ongoing process
379 and required a needs-based approach with input from nursing staff.

380 You would have to do a needs assessment around the staff and it should be a continual
381 thing not a one-off. But I think staff need to sit down together and start off deciding
382 what their needs are and then they can grow from there. (NURS24 - Nursing Home
383 Nurse)

384 All nurses reported training in pharmacology was required; some reflected on the dichotomy
385 of holding a position with legal and professional responsibility for administering a large
386 number of medications to vulnerable patients daily without full understanding of what they
387 were providing.

388 I think nurses are very guilty of sometimes handing out all these medicines and, you
389 know, we hand them out because they’re prescribed by the GP but do we really know,
390 you know, do we know the action of these drugs? Do we, you know, are we sure that
391 they’re not going interact with any of the other drugs that they have? (NURS01 –
392 Nursing home nurse)

393 All participants in this study expressed that having the appropriate skills and knowledge to
394 competently and confidently manage patients dying with dementia to a 'good death' was of
395 paramount importance.

396 I want to feel totally equipped to be able to deal with all aspects of their care and
397 never to feel that there was something extra that I could have done...Something that I
398 should have done. (NURS03 – Nursing home nurse)

399

400 **DISCUSSION**

401 This study reported on the experiences of nurses from hospice, acute care and nursing home
402 settings in managing pain for people dying with advanced dementia. Although healthcare
403 policy and clinical guidelines identify symptom management, including pain, as a
404 cornerstone of care at end of life, participant experiences reported in this study illustrated that
405 nurses can find this highly challenging to achieve in practice (van der Steen *et al.* 2014). This
406 study found that pain management in the final weeks of life was impacted by a number of
407 patient-related, nurse-related and organisational factors. Whilst patient-related factors
408 appeared to be universal across the settings, nurse-related and organisational factors varied
409 between care settings, differentially impacting on nurses' experiences of pain management.

410 *Challenges administering analgesia*

411 Administration of analgesia was a challenge for all nurses in this study due to patient refusal
412 and/or limited routes of administration. Most believed that patients' severe cognitive
413 impairment and loss of communication inhibited their recognition of analgesia as such and
414 their understanding of its need, prompting refusal. Many nurses were empathetic towards
415 patients' perspectives but felt restricted in their approaches to encouraging compliance in the
416 absence of the nurse-patient dialogue. Difficulties in nurse-patient communication in

dementia are well recognised and methods to improve this have been well-researched; however, our findings suggest that many of these strategies may remain in the literature and fail to translate into clinical practice (Finke *et al.* 2008, Weitzel *et al.* 2011). Patients' physical decline (dysphagia, low body musculature etc.) and/or altered states of consciousness (drowsiness, excessive sleep etc.) limited routes by which analgesia could be administered. Oral, intravenous and subcutaneous administration were considered problematic and perceived to present a high risk of injury, pain and distress to dying patients. Most participants preferred the use of suppositories and transdermal patches, considering them to be low risk and less invasive. Our findings did not elucidate whether difficulties with administration resulted in non-compliance. There has been surprisingly little investigation into the challenges of medication administration in dementia, despite the serious implications of non-compliance for patient outcomes; this area warrants further investigation (Passmore *et al.* 2010).

The nurse-physician relationship

In this study, nurse-physician relationships appeared to be differentially impacted by care setting. Whilst hospice nurses unanimously reported good working relationships with physicians, acute care and nursing home nurses reported mixed experiences. Positive relationships were characterised by nurses' perceptions that their contribution towards patient care was valued, that they were working in collaborative partnership with physicians and where there was mutual professional respect. Difficult nurse-physician relationships were reported where nurses described themselves as working in parallel with physicians, where participants perceived physicians to be reluctant to assist with complex cases, and/or where pain was inadequately managed. Highly experienced nurses described instances where nurse-physician relationships were negatively impacted by poor communication skills and

441 inadequate reporting among nursing staff, sometimes resulting in inappropriate patient
442 treatment.

443 The setting-specific differences in nurse-physician relationships reported here may, in part,
444 reflect the palliative focus of the hospice setting, its ethos, the relative stability and continuity
445 of staff and availability of additional organisational resources. Staff turnover in acute care
446 and nursing home settings may inhibit the establishment and development of close working
447 relationships between nursing and medical staff, particularly in the nursing home context
448 where physicians are based in external surgeries (Tjia *et al.* 2009). Nurse-physician
449 communication and relationships have been studied extensively and positive relationships
450 have been reported to result in higher job satisfaction for nurses and physicians, sharing of
451 disciplinary knowledge and improved patient outcomes (Prescott & Bowen 1985, Keenan *et*
452 *al.* 1998, Manojlovich 2010). Difficult relationships have resulted in poor job satisfaction,
453 feelings of professional isolation, and errors in patient assessment and management (Donchin
454 *et al.* 1995, Manojlovich 2010). Clarity in inter-professional working is essential in
455 healthcare and is critical in patient populations unable to effectively communicate their
456 needs; however, these relationships are complex and often impacted by professional
457 boundaries, personal perceptions and organisational cultures.

458 *Interactive learning and development*

459 Hospice nurses were satisfied with the quantity and quality of opportunities for professional
460 development. Acute care and nursing home nurses; however, experienced significant barriers
461 to accessing training and practice development due to financial, travel and time constraints.
462 Some nurses received no training in dementia; this is a significant concern given the
463 complexities of these patients, their need for tailored care, the prevalence of dementia in these
464 settings and the substantial evidence reporting poor outcomes for pain assessment and

60

management in dementia as a result of inadequately trained staff (Brunier *et al.* 1995, Closs 1996, Kovach *et al.* 2000, Weiner & Rudy 2002, Auret & Schug 2005, Plaisance & Logan 2006, Barry *et al.* 2012, Ghandehari *et al.* 2013).

Most respondents believed that learning through case-based discussion and/or mentoring by senior nurses were most likely to stimulate practice development and change. These opportunities needed to be ongoing and developed in consideration of nurses' needs. Participants emphasised that pharmacological training was required, with some expressing concern regarding their lack of understanding of the regimens they administered. This is a key area of practice development given the available evidence regarding inadequate pharmacology knowledge among nursing staff and medication administration errors, omissions and adverse events (McBride-Henry & Foureur 2006, Dilles *et al.* 2011).

These findings provide new insight into the experiences of nurses across three care settings in which patients dying with advanced dementia commonly end their lives and the gap between healthcare policy and clinical recommendations for pain management at end of life. Nurses' experiences revealed a number of barriers to pain management at end of life some of which corroborate those reported in Brörson *et al.* 2014. In addition, our findings highlight areas across and between settings in which nurses are under-supported and may be inadequately equipped to meet standards expected by policy makers.

Limitations

The nature of the self-selecting sample may have encouraged participation from nurses with an interest in research and those who felt comfortable describing experiences that included accounts of low confidence or competence, or which provided critical accounts of nursing staff and/or care organisations. Nursing home staff comprised 50% of the total sample.

1
2
3 489 However, within whole-group analyses, nursing home nurses' experiences did not differ
4
5 490 substantially from those of acute care and hospice nurses, and in other cases, their
6
7 491 experiences reflected those of acute care nurses suggesting that the core themes emerging are
8
9 492 not substantially biased to the nursing home context. It is acknowledged that acute care
10
11 493 nurses were recruited from care of the elderly units linked to teaching hospitals and are likely
12
13 494 to display greater awareness of pain in dementia than acute care nurses working in other
14
15 495 wards. The findings reported here represent the commonalities of experience and perspectives
16
17 496 of this participant sample, drawn from three different care settings and are likely to be
18
19 497 reflective of nurses working with the same patient population in the same contexts of care
20
21 498 (Mays & Pope 1995).

29 500 **CONCLUSIONS**

30
31 501 This study provides a comprehensive exploration of nurses' experiences of pain management
32
33 502 for people with advanced dementia in their final month of life. The findings indicate that
34
35 503 whilst nurses' beliefs about pain management accord with policy and clinical
36
37 504 recommendations for pain management in the final weeks of life, nurses face many
38
39 505 challenges in its achievement in practice. The inequality of training and development
40
41 506 opportunities for hospice, nursing home and acute care nurses is a concern, given that the
42
43 507 rates of referral to hospice and palliative care for people with dementia are consistently lower
44
45 508 than those for people with cancer and other comorbid conditions. Dementia care literature has
46
47 509 experienced significant expansion in recent years resulting in many empirically supported
48
49 510 recommendations for appropriate, holistic, person-centred care for this patient population
50
51 511 which often rely on the availability of appropriately equipped, well-trained staff who are
52
53 512 confident and competent to provide this care. It is imperative that nurses are adequately

513 supported and equipped with the appropriate knowledge and skills to efficiently manage the
514 needs of what is widely recognised as a complex patient population.

515

516 **RELEVANCE TO CLINICAL PRACTICE**

517 People dying with advanced dementia have complex care requirements including pain and
518 symptom management; however, in order for nurses to meet standards of care expected of
519 them, nurses require adequate and appropriate support from healthcare providers. The current
520 study indicates that acute care and nursing home nurses experience challenges in managing
521 pain for people with advanced dementia in the final month, and are at risk of being
522 undertrained and under-resourced to meet these challenges. Nurses across all healthcare
523 settings in this study self-reported a critical lack of understanding of pharmacology which
524 carries serious implications for patient safety. These findings have been used to develop and
525 pilot an interactive learning and practice development intervention appropriate for all nurses
526 working in dementia, aimed at providing opportunities for sharing knowledge and skills,
527 ongoing professional development and participation in a collaborative approach to patient
528 care. Future work should examine other methods of interactive learning and ways to improve
529 access to practice development.

Table 2. Core themes and sub-themes identified in within-group and cross-group analysis

Core theme	Sub-theme
Challenges administering analgesia	(a) Medication refusal
	(b) Route of administration
The nurse-physician relationship	(a) Positive relationships
	(b) Difficult relationships
Interactive learning and practice development	(a) Hospice nurses
	(b) Acute care and nursing home nurses
	(c) Whole-group perspectives on interactive learning and development
